

# P0 — Project Bootstrap Framework

## Extension for the A2C Architecture-to-Code Framework

Phase Zero scaffolding: project structure, build manifest, git config, env templates, Docker, Makefile

Built on: A2C Framework | E2A Architecture Framework

[github.com/subhamviky/a2c-framework](https://github.com/subhamviky/a2c-framework)

Author: Subham Gupta, Staff Architect & AI Architect

### 1. EXECUTIVE SUMMARY

The A2C Framework generates enterprise-grade microservice code, Terraform IaC, and GitHub Actions CI/CD pipelines using E2A-governed agents. However, before A2C's RequirementsAgent can begin, the target project must exist as a valid, compilable workspace: a Maven project with a pom.xml and correct directory tree, or a Poetry project with pyproject.toml and package structure. This Phase Zero bootstrapping was previously manual — a gap between specification and generation.

The P0 Framework fills this gap. It is a new abstract class alongside A2C — not an extension of it — that provides a single public entry point to generate everything a project needs before any AI-based code generation begins. The developer provides a ScaffoldRequest (from a JSON config file, a natural-language prompt, or an inline dict). P0 creates the entire project scaffold: directory tree, build manifest, dependency configuration, git rules, environment templates, README skeleton, LICENSE, Dockerfile, and Makefile.

#### Architecture Decision — New Class, Not Extension

P0 and A2C are separate concerns on different lifecycles. Bootstrap runs once per project; A2C runs whenever a new service or component is generated. Making P0 an extension of A2C would force bootstrap to execute on every A2C call. The correct design: two independent classes composable via BootstrapAndGenerateWorkflow, each callable alone or in sequence.

| Aspect             | P0 Framework                                                                  | A2C Framework                                                                  |
|--------------------|-------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Purpose            | Generate project structure, build manifest, git config, Docker, Makefile      | Generate microservice code, Terraform IaC, GitHub Actions CI/CD                |
| Input              | ScaffoldRequest (runtime, build_tool, platform, dependencies)                 | DevRequest (project_type, mandatory_nfrs, target_cloud, context)               |
| Public entry point | bootstrapper.bootstrap(request, config)                                       | sdhc_agent.run(dev_request, config)                                            |
| Output             | ScaffoldResult (scaffolded_files, project_root, build_manifest_path)          | DevRequest (generated_code, generated_iac, generated_cicd, critic_report)      |
| Runs when          | Once per project — at project creation                                        | As needed — whenever a new component is generated                              |
| Lifecycle          | Phase Zero — before any business logic                                        | Phase 2-7 — NFR-First development sequence                                     |
| NFR enforcement    | Structural: correct gitignore, non-root Docker, HEALTHCHECK, Makefile targets | Contract: _apply_policy() injects idempotency, circuit breakers, observability |
| Composable?        | Yes — BootstrapAndGenerateWorkflow chains P0 -> A2C                           | Yes — chains from P0 result via dev_request handoff                            |

## 2. FRAMEWORK ARCHITECTURE

### 2.1 Class Hierarchy

P0 follows the same E2A Template Method Pattern as A2C and E2A. One PUBLIC method (bootstrap) contains the full orchestration sequence. All domain-specific behaviour is in PROTECTED methods that subclasses override. Infrastructure mechanics (file I/O, idempotency, config loading) are in PRIVATE methods that subclasses never touch.

```
BaseProjectBootstrapper (ABC)          - abstract base, one public entry point
|
+-- PythonPoetryBootstrapper           - Python 3.x + Poetry
+-- PythonPipBootstrapper               - Python 3.x + pip / setup.cfg
+-- JavaMavenBootstrapper               - Java 21 + Maven / Spring Boot
+-- JavaGradleBootstrapper             - Java 21 + Gradle (Kotlin DSL)
+-- NodeNpmBootstrapper                - Node.js + npm / package.json
+-- GoModulesBootstrapper              - Go + go.mod

ProjectBootstrapperFactory              - resolves subclass from ScaffoldRequest

BootstrapAndGenerateWorkflow            - orchestrates P0 -> A2C in sequence
```

### 2.2 TypedDicts

#### ScaffoldRequest — input to bootstrap()

| Field               | Type      | Required           | Description                                                                       |
|---------------------|-----------|--------------------|-----------------------------------------------------------------------------------|
| source              | str       | No                 | 'json'   'prompt'   'inline' (default: inline)                                    |
| config_path         | str       | If source='json'   | Path to scaffold-config.json                                                      |
| prompt              | str       | If source='prompt' | Free-text description for LLM parsing                                             |
| runtime             | str       | Yes                | 'python'   'java'   'node'   'go'                                                 |
| runtime_version     | str       | No                 | '3.12'   '21'   '20'   '1.22'                                                     |
| platform            | str       | Yes                | 'aws'   'gcp'   'azure'   'standalone'                                            |
| project_name        | str       | Yes                | PascalCase: 'SettlementEngine'                                                    |
| package_name        | str       | Python only        | snake_case: 'settlement_engine'                                                   |
| group_id            | str       | Java only          | 'com.company.domain'                                                              |
| artifact_id         | str       | Java only          | kebab-case: 'settlement-engine'                                                   |
| build_tool          | str       | Yes                | 'poetry'   'pip'   'maven'   'gradle'   'npm'   'go_modules'                      |
| project_type        | str       | No                 | 'fastapi_microservice'   'spring_boot'   'lambda'   'langgraph_agent'   'library' |
| dependencies        | List[str] | No                 | Runtime deps: ['fastapi>=0.111', 'pydantic>=2.7']                                 |
| dev_dependencies    | List[str] | No                 | Dev/test deps: ['pytest>=8', 'ruff>=0.4']                                         |
| spring_boot_version | str       | Java only          | Default: '3.3.0'                                                                  |
| java_source_version | str       | Java only          | Default: '21'                                                                     |
| output_path         | str       | No                 | Base output dir (default: './')                                                   |
| license             | str       | No                 | 'Apache-2.0'   'MIT'   'PROPRIETARY' (default: Apache-2.0)                        |
| include_docker      | bool      | No                 | Generate Dockerfile + .dockerignore (default: true)                               |
| include_makefile    | bool      | No                 | Generate Makefile (default: true)                                                 |

#### ScaffoldResult — output from bootstrap()

| Field               | Type        | Description                                                   |
|---------------------|-------------|---------------------------------------------------------------|
| success             | bool        | True if all required files were created and validated         |
| scaffold_key        | str         | Business idempotency key: name:runtime:build_tool:platform    |
| project_root        | str         | Absolute path to created project root directory               |
| scaffolded_files    | List[str]   | Absolute paths of every file created                          |
| build_manifest_path | str         | Path to pom.xml / pyproject.toml / go.mod                     |
| readme_path         | str         | Path to generated README.md                                   |
| trace_id            | str         | UUID correlation ID for observability                         |
| latency_ms          | float       | Total execution time in milliseconds                          |
| errors              | List[str]   | Error messages if success=False                               |
| dev_request         | dict   None | A2C DevRequest — populated when config['a2c']['enabled']=True |

### 3. BASEPROJECTBOOTSTRAPPER — FULL CLASS CONTRACT

#### 3.1 Class Variables

| Variable             | Type                | Default                            | Purpose                                                                                         |
|----------------------|---------------------|------------------------------------|-------------------------------------------------------------------------------------------------|
| bootstrapper_name    | str                 | 'BaseProjectBootstrapper'          | Governance key — set in every subclass. Used in all structured log entries.                     |
| idempotency          | bool                | True                               | When True: skip if project directory already exists and is non-empty. Set False to re-scaffold. |
| APPROVED_RUNTIMES    | List[str]           | ['python','java','node','go']      | Governance allow-list for runtime field.                                                        |
| APPROVED_PLATFORMS   | List[str]           | ['aws','gcp','azure','standalone'] | Governance allow-list for platform field.                                                       |
| APPROVED_BUILD_TOOLS | Dict[str,List[str]] | See class                          | Per-runtime allow-list for build_tool field.                                                    |
| MANIFEST_FILENAMEES  | Dict[tuple,str]     | See class                          | Maps (runtime, build_tool) to correct manifest filename.                                        |

#### 3.2 Method Contract Table

| ACCESS           | METHOD SIGNATURE                                       | RETURNS         | PURPOSE / WHEN TO OVERRIDE                                                          |
|------------------|--------------------------------------------------------|-----------------|-------------------------------------------------------------------------------------|
| <b>PUBLIC</b>    | bootstrap(request, config, **kwargs)                   | ScaffoldResult  | Single entry point. Never override. Full 16-step sequence.                          |
| <b>ABSTRACT</b>  | _validate_request(request, config, **kwargs)           | bool            | Check required fields, approved runtime/platform/build_tool. Return False to abort. |
| <b>ABSTRACT</b>  | _resolve_config(request, config, **kwargs)             | ScaffoldRequest | Load from JSON file or LLM prompt. Merge into request dict.                         |
| <b>ABSTRACT</b>  | _plan_scaffold(request, config, **kwargs)              | List[dict]      | Build [{step, file, description}] task list for observability.                      |
| <b>ABSTRACT</b>  | _scaffold_structure(request, config, root, **kwargs)   | None            | Create all directories. Call __create_directory() per path.                         |
| <b>ABSTRACT</b>  | _generate_build_manifest(request, config, **kwargs)    | str             | Return pom.xml   pyproject.toml   go.mod content as string.                         |
| <b>PROTECTED</b> | _generate_dependency_config(request, config, **kwargs) | str None        | Return requirements.txt content or None. Default: None.                             |
| <b>PROTECTED</b> | _dependency_file_name(request)                         | str             | Filename for dep config. Default: 'requirements.txt'.                               |
| <b>ABSTRACT</b>  | _generate_git_config(request, config, **kwargs)        | Dict[str,str]   | Return {'gitignore': content, '.gitattributes': content}.                           |
| <b>ABSTRACT</b>  | _generate_env_templates(request, config, **kwargs)     | Dict[str,str]   | Return {relative_path: content} for env files.                                      |
| <b>ABSTRACT</b>  | _generate_readme_scaffold(request, config, **kwargs)   | str             | Return README.md skeleton as string.                                                |
| <b>PROTECTED</b> | _generate_license(request, config, **kwargs)           | str None        | Return LICENSE text. Default: Apache-2.0. None for PROPRIETARY.                     |
| <b>ABSTRACT</b>  | _generate_docker_config(request, config, **kwargs)     | Dict[str,str]   | Return {'Dockerfile': content, '.dockerignore': content}.                           |
| <b>PROTECTED</b> | _generate_makefile(request, config, **kwargs)          | str None        | Return Makefile content. Default: None. Override per runtime.                       |
| <b>PROTECTED</b> | _validate_output(result, config, **kwargs)             | bool            | Confirm required files created. Default: checks manifest + README.                  |

| ACCESS           | METHOD SIGNATURE                                                     | RETURNS         | PURPOSE / WHEN TO OVERRIDE                                   |
|------------------|----------------------------------------------------------------------|-----------------|--------------------------------------------------------------|
| <b>PROTECTED</b> | <code>_handle_error(error, request, result, config, **kwargs)</code> | ScaffoldResult  | Log error, append to errors[], return safe result.           |
| <b>PRIVATE</b>   | <code>__load_json_config(config_path)</code>                         | ScaffoldRequest | Read scaffold-config.json['scaffold']. Never override.       |
| <b>PRIVATE</b>   | <code>__load_prompt_config(prompt, config)</code>                    | ScaffoldRequest | LLM-based config parsing. Never override.                    |
| <b>PRIVATE</b>   | <code>__write_file(root, relative_path, content)</code>              | str             | Write file + create parents. Returns absolute path.          |
| <b>PRIVATE</b>   | <code>__create_directory(path)</code>                                | None            | mkdir -p. Idempotent.                                        |
| <b>PRIVATE</b>   | <code>__generate_scaffold_key(request)</code>                        | str             | name:runtime:build_tool:platform — business idempotency key. |
| <b>PRIVATE</b>   | <code>__is_already_scaffolded(key, config)</code>                    | bool            | True if project dir exists and is non-empty.                 |
| <b>PRIVATE</b>   | <code>__resolve_output_path(request, config)</code>                  | str             | request > config > env<br>BOOTSTRAP_OUTPUT_PATH > './'       |
| <b>PRIVATE</b>   | <code>__write_build_manifest(request, root, content)</code>          | str             | Write manifest to runtime-correct filename.                  |
| <b>PRIVATE</b>   | <code>__build_dev_request(request, a2c_cfg)</code>                   | dict            | Build A2C DevRequest for P0 -> A2C handoff.                  |

#### 4. INTERNAL EXECUTION SEQUENCE — BOOTSTRAP()

The sequence below is fixed and enforced by the base class. Subclasses never modify it. Every step is logged. A failure at any step calls `_handle_error()` and returns `ScaffoldResult` with `success=False`.

| Step | Action                                     | Calls                                                                           | Condition                                                   |
|------|--------------------------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------|
| 1    | Resolve config from external source        | <code>_resolve_config()</code>                                                  | Only if source = 'json' or 'prompt'                         |
| 2    | Validate ScaffoldRequest                   | <code>_validate_request()</code>                                                | Always. Return False -> ValueError abort                    |
| 3    | Idempotency check                          | <code>__is_already_scaffolded()</code>                                          | Only if self.idempotency = True                             |
| 4    | Build scaffold plan                        | <code>_plan_scaffold()</code>                                                   | Always. Result stored in request['scaffold_plan']           |
| 5    | Create directory tree                      | <code>_scaffold_structure()</code>                                              | Always                                                      |
| 6    | Generate + write build manifest            | <code>_generate_build_manifest()</code> + <code>__write_build_manifest()</code> | Always                                                      |
| 7    | Generate dependency config                 | <code>_generate_dependency_config()</code>                                      | Only if method returns non-None                             |
| 8    | Generate git config                        | <code>_generate_git_config()</code>                                             | Only if request['git_init'] != False                        |
| 9    | Generate env templates                     | <code>_generate_env_templates()</code>                                          | Always                                                      |
| 10   | Generate README                            | <code>_generate_readme_scaffold()</code>                                        | Always                                                      |
| 11   | Generate LICENSE                           | <code>_generate_license()</code>                                                | Only if license != 'PROPRIETARY'                            |
| 12   | Generate Docker config                     | <code>_generate_docker_config()</code>                                          | Only if include_docker = True                               |
| 13   | Generate Makefile                          | <code>_generate_makefile()</code>                                               | Only if include_makefile = True                             |
| 14   | Validate output                            | <code>_validate_output()</code>                                                 | Always. Return False -> ValueError abort                    |
| 15   | Latency SLO check                          | (internal)                                                                      | Warn if > max_latency_ms (default 10,000 ms)                |
| 16   | Structured observability log + A2C handoff | (internal)                                                                      | Always. A2C handoff only if config['a2c']['enabled'] = True |

## 5. NFR ENFORCEMENT — CORRECT BY STRUCTURE

P0 enforces Non-Functional Requirements structurally, not through prompts. Every generated artifact is correct by construction:

| NFR                                       | How P0 Enforces It                                                           | Artifact            |
|-------------------------------------------|------------------------------------------------------------------------------|---------------------|
| Security — non-root container             | Dockerfile uses multi-stage build + RUN useradd/adduser (UID 1001)           | Dockerfile          |
| Security — no secrets in git              | _.gitignore excludes .env, *.key, chroma_db/, *.zip, .venv/                  | gitignore           |
| Security — health probes                  | Dockerfile includes HEALTHCHECK pointing to /health or /actuator/health      | Dockerfile          |
| Observability — env-driven config         | All LLM model IDs, cloud endpoints, OTel config in .env.example              | env.example         |
| Portability — multi-cloud                 | .env.example includes platform-specific vars for AWS/GCP/Azure               | env.example         |
| Clean Architecture — directory structure  | src/{pkg}/models/, services/, routers/, tools/ matches E2A layers            | Directory tree      |
| CI/CD readiness                           | .github/workflows/ directory created; Makefile targets match pipeline stages | Makefile + .github/ |
| Idempotency — same project not re-created | __is_already_scaffolded() checks project dir before any file writes          | bootstrap() Step 3  |
| Dev workflow — standard commands          | Makefile: install, test, lint, build, run, docker-build, clean               | Makefile            |
| Dependency pinning                        | pyproject.toml/pom.xml includes all declared deps with version ranges        | Build manifest      |
| E2A attribution                           | README scaffold includes E2A framework link and Clean Architecture layer map | README.md           |

## 6. CONFIGURATION RESOLUTION — THREE INPUT SOURCES

ScaffoldRequest can be provided from three sources. All three produce the same ScaffoldRequest TypedDict. The resolution chain for any individual field follows the same priority as E2A:

| Priority    | Source                                    | How to use                                                                             |
|-------------|-------------------------------------------|----------------------------------------------------------------------------------------|
| 1 (highest) | Inline dict (source='inline')             | Pass ScaffoldRequest directly to bootstrap(request, config)                            |
| 2           | JSON config file (source='json')          | Set request['source']='json', request['config_path']='./scaffold-config.json'          |
| 3           | Natural language prompt (source='prompt') | Set request['source']='prompt', request['prompt']='Create a FastAPI service on AWS...' |

### 6.1 JSON Configuration File — scaffold-config.json

The JSON config file contains two top-level sections: **scaffold** (required, drives P0) and **a2c** (optional, drives A2C handoff via BootstrapAndGenerateWorkflow). Both can be present in the same file to run the full pipeline with one command.

```
# scaffold-config.json — Python/Poetry example (FastAPI on AWS)
{
  "scaffold": {
    "source": "json",
    "runtime": "python",
    "runtime_version": "3.12",
    "platform": "aws",
    "build_tool": "poetry",
    "project_type": "fastapi microservice",
    "project_name": "SettlementEngine",
    "package_name": "settlement_engine",
    "output_path": "./generated/",
    "license": "Apache-2.0",
    "include_docker": true,
    "include_makefile": true,
    "dependencies": [
      "fastapi>=0.111.0", "uvicorn[standard]>=0.30.0", "pydantic>=2.7.0",

  }
}
```

## 7. GENERATED DIRECTORY STRUCTURES

### 7.1 Python FastAPI Microservice (Poetry)

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| SettlementEngine/  |                                                                 |
| pyproject.toml     | Poetry build manifest with all dependencies                     |
| .gitignore         | Python-specific: __pycache__, .venv, .env, chroma_db, *.zip     |
| .env.example       | AWS/GCP/Azure env vars + E2A NFR config                         |
| README.md          | E2A spike framing + stack badges + structure tree               |
| LICENSE            | Apache-2.0                                                      |
| Dockerfile         | Multi-stage Python build, non-root UID 1001, HEALTHCHECK        |
| .dockerignore      | .venv, __pycache__, .env, .git, tests                           |
| Makefile           | install, test, lint, build, run, docker-build, clean            |
| .github/           |                                                                 |
| workflows/         | CI/CD workflow directory (A2C fills this in Phase 4)            |
| src/               |                                                                 |
| settlement_engine/ |                                                                 |
| __init__.py        |                                                                 |
| main.py            | FastAPI app entry point placeholder                             |
| config/            | Configuration classes                                           |
| __init__.py        |                                                                 |
| models/            | Pydantic BaseModel domain entities (E2A: AgentState equivalent) |
| __init__.py        |                                                                 |
| services/          | Business logic classes (E2A: BIMP / @Service equivalent)        |
| __init__.py        |                                                                 |
| routers/           | FastAPI APIRouter (E2A: OData Service Binding equivalent)       |
| __init__.py        |                                                                 |
| tools/             | MCP tool classes (E2A: BaseToolService subclasses)              |
| __init__.py        |                                                                 |
| tests/             |                                                                 |
| __init__.py        |                                                                 |
| conftest.py        | Pytest fixtures                                                 |

### 7.2 Python LangGraph Agent (Poetry)

Same base structure as FastAPI microservice plus:

|                        |                                                          |
|------------------------|----------------------------------------------------------|
| SettlementEngine/      |                                                          |
| ... (all files above)  |                                                          |
| src/settlement_engine/ |                                                          |
| agents/                | BaseAgent subclasses (RouterAgent, KnowledgeAgent, etc.) |
| __init__.py            |                                                          |
| rag/                   | BaseRAGPipeline subclasses                               |
| __init__.py            |                                                          |
| workflows/             | BaseWorkflow subclasses (LangGraph StateGraph)           |
| init .py               |                                                          |

### 7.3 Java Spring Boot (Maven)

|                              |                                                          |
|------------------------------|----------------------------------------------------------|
| FinancialSettlementPlatform/ |                                                          |
| pom.xml                      | Maven POM with Spring Boot parent, all dependencies      |
| .gitignore                   | Java: target/, *.class, .idea/, *.jar, .gradle/          |
| README.md                    | E2A spike framing + Spring Boot stack badges             |
| LICENSE                      | Apache-2.0                                               |
| Dockerfile                   | Multi-stage eclipse-temurin build, non-root, HEALTHCHECK |
| .dockerignore                | target/, .git, .idea, *.md                               |
| Makefile                     | build, test, run, docker-build, clean                    |
| .github/                     |                                                          |
| workflows/                   | CI/CD directory (A2C fills in Phase 4)                   |
| src/                         |                                                          |
| main/                        |                                                          |
| java/com/subhamviky/         |                                                          |
| config/                      | Spring @Configuration classes                            |
| domain/                      | JPA @Entity classes (E2A: CDS View Entity equivalent)    |
| service/                     | @Service classes (E2A: BIMP equivalent)                  |
| controller/                  | @RestController (E2A: OData Service Binding equivalent)  |

| resources/                   |                                                          |

```
    application.yml           Default Spring Boot config with actuator, logging
    application-dev.yml       Dev profile (show-sql: true)
    application-prod.yml      Prod profile (logging WARN)
test/
  java/com/subhamviky/
    FinancialSettlementPlatformApplicationTests.java
```

## 8. CONCRETE IMPLEMENTATIONS — QUICK REFERENCE

| Class                    | Runtime     | Build Tool | Project Types Supported                                | Key Overrides                                                                                                                                                               |
|--------------------------|-------------|------------|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PythonPoetryBootstrapper | Python 3.x  | Poetry     | fastapi_microservice, lambda, langgraph_agent, library | All abstract methods. <code>_generate_makefile()</code> : poetry commands.                                                                                                  |
| PythonPipBootstrapper    | Python 3.x  | pip        | fastapi_microservice, lambda, library                  | <code>_generate_build_manifest()</code> : <code>setup.cfg</code> . <code>_generate_dependency_config()</code> : <code>requirements.txt</code> .                             |
| JavaMavenBootstrapper    | Java 21+    | Maven      | spring_boot, library                                   | All abstract methods. <code>pom.xml</code> with <code>spring-boot-starter-parent</code> .                                                                                   |
| JavaGradleBootstrapper   | Java 21+    | Gradle     | spring_boot, library                                   | <code>_generate_build_manifest()</code> : <code>build.gradle.kts</code> . <code>_generate_makefile()</code> : gradle wrapper commands.                                      |
| NodeNpmBootstrapper      | Node.js 20+ | npm        | express_api, next_app, library                         | <code>_generate_build_manifest()</code> : <code>package.json</code> with scripts.                                                                                           |
| GoModulesBootstrapper    | Go 1.22+    | go_modules | http_service, cli, library                             | <code>_generate_build_manifest()</code> : <code>go.mod</code> . <code>_scaffold_structure()</code> : <code>cmd/</code> , <code>internal/</code> , <code>pkg/</code> layout. |

### 8.1 Factory — ProjectBootstrapperFactory

The factory resolves the correct subclass from a `ScaffoldRequest` without the caller knowing which class to instantiate. It follows the same approved-list governance pattern as E2A agent routing.

```
# Resolve and run — single call
bootstrapper = ProjectBootstrapperFactory.create(request, config)
result = bootstrapper.bootstrap(request, config)

# Register a new bootstrapper (call at module import time)
ProjectBootstrapperFactory.register('go', 'go_modules', GoModulesBootstrapper)
```

## 9. BOOTSTRAPANDGENERATEWORKFLOW — COMPOSING P0 WITH A2C

BootstrapAndGenerateWorkflow orchestrates the complete pipeline: P0 scaffold followed by A2C code generation. It reads a single scaffold-config.json that contains both the scaffold section (for P0) and the a2c section (for A2C). Three operating modes:

| Mode                    | How to invoke                                 | What runs                                       |
|-------------------------|-----------------------------------------------|-------------------------------------------------|
| Bootstrap only          | execute(request, config, bootstrap_only=True) | P0 only — creates project structure, exits      |
| Generate only           | execute(request, config, generate_only=True)  | A2C only — assumes project already bootstrapped |
| Full pipeline (default) | execute(request, config)                      | P0 scaffold -> A2C code generation in sequence  |

### 9.1 Full Pipeline Execution Sequence

```
BootstrapAndGenerateWorkflow.execute(scaffold_request, config)

Step A — P0 Phase (BaseProjectBootstrapper.bootstrap)
1 resolve config (JSON/prompt/inline)
2 validate ScaffoldRequest
3 idempotency check
4 create directory structure
5 generate build manifest (pom.xml / pyproject.toml)
6 generate git config, env templates, README, LICENSE, Dockerfile, Makefile
7 validate output
8 build dev request for A2C handoff

Step B — A2C Phase (SDLCAssistantAgent.run) — only if a2c.enabled=true
1 RequirementsAgent validates project_type, mandatory_nfrs
2 IaCAgent generates Terraform (ECS/EKS/Cloud Run)
3 CodeGenAgent generates Clean Architecture microservice code
4 CICDAgent generates GitHub Actions with OIDC, RAGAS, Trivy
5 CodeCriticAgent validates NFR completeness score >= 0.75

Output: {scaffold_result: ScaffoldResult, generation_result: DevRequest}
```

### 9.2 A2C Handoff — dev\_request Population

When config['a2c']['enabled'] is True, bootstrap()'s Step 16 (observability log) calls the private \_\_build\_dev\_request() method, which maps ScaffoldRequest fields to A2C's DevRequest TypedDict. Fields from both the scaffold section and the a2c section contribute to the handoff payload:

| DevRequest field | Source                                                                 |
|------------------|------------------------------------------------------------------------|
| project_name     | From ScaffoldRequest['project_name']                                   |
| language         | From ScaffoldRequest['runtime'] (python/java)                          |
| target_cloud     | From ScaffoldRequest['platform'] (aws/gcp/azure)                       |
| project_type     | From config['a2c']['project_type']                                     |
| mandatory_nfrs   | From config['a2c']['mandatory_nfrs'] (A2C adds missing mandatory ones) |
| context          | From config['a2c']['context']                                          |

## 10. USAGE PATTERNS

---

### Pattern 1 — Bootstrap only (inline request)

```
from base_project_bootstrapper import ProjectBootstrapperFactory

request = {
    'source': 'inline',
    'runtime': 'python',
    'runtime_version': '3.12',
    'platform': 'aws',
    'build_tool': 'poetry',
    'project_type': 'fastapi_microservice',
    'project_name': 'SettlementEngine',
    'package_name': 'settlement engine',
    'license': 'Apache-2.0',
    'include_docker': True,
    'dependencies': ['fastapi>=0.111', 'pydantic>=2.7', 'structlog>=24.1'],
    'dev_dependencies': ['pytest>=8', 'ruff>=0.4'],
}

bootstrapper = ProjectBootstrapperFactory.create(request)
result = bootstrapper.bootstrap(request)

print(result['project_root']) # /abs/path/SettlementEngine
print(len(result['scaffolded_files'])) # e.g. 18
print(result['success']) # True
```

### Pattern 2 — Bootstrap from JSON file

```
request = { 'source': 'json', 'config_path': './scaffold-config.json' }
bootstrapper = ProjectBootstrapperFactory.create(
    {'runtime': 'python', 'build_tool': 'poetry'} # factory needs these to route
)
result = bootstrapper.bootstrap(request)
```

### Pattern 3 — Full pipeline: P0 scaffold + A2C generation

```
from base_project_bootstrapper import BootstrapAndGenerateWorkflow

config = {
    'output_path': './generated/',
    'a2c': {
        'enabled': True,
        'project_type': 'FastAPI Microservice',
        'mandatory_nfrs': ['Idempotency', 'Observability'],
        'target_cloud': 'aws',
        'context': 'Financial settlement with saga orchestration'
    }
}

request = {
    'source': 'json',
    'config_path': './scaffold-config.json',
    'runtime': 'python',
    'build_tool': 'poetry',
}

workflow = BootstrapAndGenerateWorkflow(config=config)
result = workflow.execute(request, config)

print(result['scaffold_result']['scaffolded_files'])
print(result['generation_result']['dev_request'])
```

#### Pattern 4 — Disable idempotency (re-scaffold existing project)

```
bootstrapper = PythonPoetryBootstrapper(config=config)
bootstrapper.idempotency = False    # override: re-scaffold even if dir exists
result = bootstrapper.bootstrap(request, config)
```

#### Pattern 5 — Prompt-driven scaffolding (LLM config resolution)

```
request = {
    'source': 'prompt',
    'prompt': 'Create a Python FastAPI microservice on AWS for payment reconciliation.'
              ' Use Poetry. Include Docker and Makefile. License: Apache-2.0.',
    'runtime': 'python',    # factory routing still needs these
    'build_tool': 'poetry',
}
config = { 'model id': 'anthropic.claude-3-5-sonnet-20241022-v2:0' }

bootstrapper = PythonPoetryBootstrapper(config=config)
result = bootstrapper.bootstrap(request, config)
```

## 11. IMPLEMENTATION CHECKLIST — NEW BOOTSTRAPPER SUBCLASS

Follow this checklist when adding a new runtime or build tool. All items are mandatory except those marked optional.

| #  | Task                                                                                                   | Mandatory?  |
|----|--------------------------------------------------------------------------------------------------------|-------------|
| 1  | Define bootstrapper_name class attribute (e.g. 'NodeNpmBootstrapper')                                  | Yes         |
| 2  | Call ProjectBootstrapperFactory.register(runtime, build_tool, MyBootstrapper)                          | Yes         |
| 3  | Override _validate_request(): check required fields for this runtime                                   | Yes         |
| 4  | Override _resolve_config(): handle source='json' + source='prompt' loading                             | Yes         |
| 5  | Override _plan_scaffold(): return [{step, file, description}] task list                                | Yes         |
| 6  | Override _scaffold_structure(): call __create_directory() for every dir in the tree                    | Yes         |
| 7  | Override _generate_build_manifest(): return full file content as string                                | Yes         |
| 8  | Override _generate_git_config(): runtime-correct .gitignore (exclude build artifacts, .env, IDE)       | Yes         |
| 9  | Override _generate_env_templates(): {relative_path: content} for all env config files                  | Yes         |
| 10 | Override _generate_readme_scaffold(): project name, badges, E2A link, structure tree, get-started      | Yes         |
| 11 | Override _generate_docker_config(): multi-stage, non-root UID 1001, HEALTHCHECK                        | Yes         |
| 12 | Override _generate_dependency_config() + _dependency_file_name() if deps not in manifest               | If pip/yarn |
| 13 | Override _generate_makefile(): standard targets (install, test, lint, build, run, docker-build, clean) | Recommended |
| 14 | Override _validate_output(): add runtime-specific checks beyond manifest + README                      | Recommended |
| 15 | Override _generate_license() only to add full license text; default Apache-2.0 is provided             | Optional    |
| 16 | Override _handle_error() to add alerting, cleanup, or partial-state recovery                           | Recommended |
| 17 | DO NOT override bootstrap() — the 16-step sequence is enforced by the base class                       | Never       |
| 18 | DO NOT call any private method (__write_file etc.) from outside the class                              | Never       |

## 12. ENVIRONMENT VARIABLE REFERENCE

| Variable                 | Used in                 | Default   | Controls                                     |
|--------------------------|-------------------------|-----------|----------------------------------------------|
| BOOTSTRAP_OUTPUT_PATH    | __resolve_output_path() | './'      | Base directory for all generated projects    |
| BOOTSTRAP_MAX_LATENCY_MS | bootstrap() Step 15     | 10000     | Latency SLO threshold in milliseconds        |
| LLM_MODEL_ID             | __load_prompt_config()  | 'default' | LLM model for prompt-based config resolution |
| TOOL_TIMEOUT             | BaseToolService (A2C)   | 5.0       | HTTP timeout for A2C tool calls (inherited)  |
| MIN_CONFIDENCE           | BaseAgent (A2C)         | 0.85      | RAGAS groundedness gate (inherited from E2A) |

## 13. PO IN THE FULL E2A / A2C / PO FRAMEWORK CONTEXT

The three frameworks form a layered stack. Each addresses a distinct concern. All follow the same E2A Template Method Pattern.

| Framework          | Concern                                              | Entry point                             | Input           | Output                                                             |
|--------------------|------------------------------------------------------|-----------------------------------------|-----------------|--------------------------------------------------------------------|
| E2A                | Build governed agentic AI systems                    | agent.run(state, config)                | AgentState      | Updated AgentState with response, tokens, trace_id                 |
| A2C                | Generate governed microservice code using E2A agents | sdlc_agent.run(dev_request, config)     | DevRequest      | generated_code, generated_iac, generated_cicd, critic_report       |
| PO (this document) | Generate project structure before A2C runs           | bootstrapper.bootstrap(request, config) | ScaffoldRequest | project_root, pom.xml/pyproject.toml, Dockerfile, Makefile, README |

```
Developer has an idea for a new microservice
|
v
[P0] ProjectBootstrapperFactory.create(request)
    bootstrapper.bootstrap(request, config)
        |
        | generates: pyproject.toml / pom.xml, directory tree,
        |             Dockerfile, Makefile, .gitignore, .env.example
        |
        v
[A2C] SDLCWorkflow.execute(dev_request, config)
    RequirementsAgent -> CodeGenAgent -> IaCAgent -> CICDAgent -> CodeCriticAgent
        |
        | generates: service classes, RAG pipeline, Terraform, GitHub Actions
        |
        v
[E2A] All generated agent/service code inherits BaseAgent, BaseRAGPipeline,
      BaseToolService - NFRs enforced as structural contracts at runtime
```
